

# Parsons Problems

```
# data columns are (est1970, hi1970, lo1970, est1971, hi1971, lo1971, ...)  
# Use this function to produce (year, est, hi, lo) for one year given the index  
# of the first column.
```

```
strip <- function(data, start, year) {  
  rename(estimate = 1, hi = 2, lo = 3)  
  select(data, start:(start + 2))  
  select(year, everything())  
  mutate(year = rep(year, num_rows))  
}
```

# Create a Faded Example

1. Think of a small pattern you frequently use when programming.
2. Write down an example of it.
3. Identify the related parts that you would fade when creating a set of similar examples.
